ROTAVIRUS VACCINES

PART D GUIDELINES FOR NATIONAL REGULATORY AUTHORITIES
D.1. General .................................................................
D.2 Release and certification .............................................

Adopted by the 56th meeting of the WHO Expert Committee on Biological Standardization, 24-28 October 2005. A definitive version of this document, which will differ from this version in editorial but not scientific detail, will be published in the WHO Technical Report Series.
This document provides guidance to National Regulatory Authorities (NRAs) and vaccine manufacturers on the production, quality control and evaluation of safety and efficacy of live attenuated rotavirus vaccines (oral) by outlining, in detail, international regulatory expectations for product characterization. It should be read in conjunction with the WHO guidelines on nonclinical evaluation of vaccines (1), and the WHO guidelines on clinical evaluation of vaccines: regulatory expectations (2), in order to understand the whole process of vaccine evaluation. Advice that is specific to the nonclinical or clinical evaluation of live attenuated rotavirus vaccines is provided to supplement these two generic documents.

The following text is written in the form of guidelines instead of recommendations. Guidelines allow greater flexibility than recommendations with respect to expected future developments in the field.

INTRODUCTION

The high incidence of rotavirus disease around the world has prompted international agencies including the World Health Organization (WHO), the Global Alliance for Vaccines and Immunization (GAVI), Children’s Vaccine Program and the Rotavirus Vaccine Programme at the Program for Appropriate Technology in Health (PATH) to identify rotavirus vaccine development as one of their highest priority. In response to this interest in the development of candidate rotavirus vaccines, WHO held an informal consultation meeting on the Quality, Safety and Efficacy Specifications for Live Attenuated Rotavirus Vaccines in Mexico City, 8-9 February 2005 (15). It was considered timely by the experts present for WHO to develop production and quality control guidelines and technical specifications for these vaccines. Draft guidelines on production and quality control specifications for live attenuated rotavirus vaccine (oral) were developed by a small drafting group established by WHO and were comprehensively reviewed by a WHO Informal Consultation on proposed WHO Guidelines to Assure the Quality, Safety and Efficacy of Live Attenuated Rotavirus Vaccines in Geneva, 29-30 August 2005. Taking into account the comments made during the consultation, the revised document was submitted to and
approved by the 56th meeting of the WHO Expert Committee on Biological Standardization (ECBS), 24-28 October 2005.

The scope of this document covers live attenuated rotavirus vaccines (oral), and vaccine candidates, that are intended for international use. The aim of vaccination against rotavirus infection is to induce immunity against relevant rotavirus serotypes in one series of inoculations for the prevention of rotavirus gastroenteritis. The prevalence of multiple and different rotavirus serotypes throughout the world complicates vaccine development strategies. According to data available in 2005, the majority of rotavirus disease in human is caused by five distinct serotypes of rotavirus, designated G1, G2, G3, G4 and G9 based upon the molecular composition of one outer coat viral protein (VP7). In the last decade intense rotavirus surveillance and improved laboratory assay methods have resulted in the detection of additional G serotypes that play a role in human disease. Although serotypes G1-G4 are still the predominant serotypes around the world, serotype G5, G8 and G9 have been isolated in Latin America, Africa and India respectively and are beginning to cause a higher percentage of disease. The relative benefit for monovalent, multivalent or regional specific vaccines is unclear until efficacy data demonstrating heterotypic protection against relevant rotavirus serotypes are available.

The scope of this document is restricted to live vaccines, but the properties of the possible candidates are varied, particularly with respect to their degree of attenuation. This affects the extent to which they grow in culture and in the human gut and applies to current and previous strains investigated. There will therefore be major quality issues specific to a particular vaccine, such as the assay of vaccine potency, the stability of the virus in production, the yield of virus and the extent of contamination by cell derived materials. Clinical issues which will vary between candidates include the dose required to immunize, the possibility of transmission to contacts of vaccinees and the genetic stability of the virus on replication in the gut of recipients. While many of the points of possible concern are generic and considered in this document, it must be remembered that each candidate must be examined individually and may raise significant product specific issues.

There are a number of oral rotavirus vaccines currently approved or in various stages of vaccine development. Each vaccine is the result of an unique approach in developing an attenuated phenotype and for the prevention of rotavirus disease. As more vaccines become readily available around the world, data will be provided to help shaping decisions on future vaccine compositions. Examples of vaccines approved or in development include multivalent human-bovine and human-rhesus reassortant vaccines and monovalent vaccines containing a single attenuated human rotavirus strain, natural human-bovine reassortants or animal rotavirus strains. Vaccines that have completed controlled efficacy studies have demonstrated high levels of efficacy (>80%) against severe rotavirus gastroenteritis, also have shown a range of heterotypic protection against multiple serotypes. The impact of vaccine introduction on the epidemiology of natural rotavirus infection is as yet unknown.

All of the vaccine candidates are claimed to be attenuated, however, the basis for the attenuation phenotype of current vaccine candidates is unknown. Typically the method of attenuation is to exploit the host range restriction properties of animal rotaviruses (Jennerian) by laboratory or natural (neonatal rotavirus strains) genetic reassortment with human rotavirus with the desired serotypes or insertion of multigenic mutations by serial passage in cell culture. Since laboratory markers of attenuation are not well defined and animal models demonstrating
attenuation are not readily available, the claim of attenuation is based on clinical experience in human subjects. How the product will behave in clinical use is therefore based on clinical trials and consistency of production rather than any specific laboratory tests. Potential laboratory markers of product consistency include genetic sequence information on the virus seed to show that a new seed material is similar to the previous seed and that each could be distinguished from the parent virus. Multiple passages of virus seed materials under defined cell culture conditions as well as vaccine virus isolated from stool samples of vaccinees may be helpful to generate data on the conditions favouring genetic stability of the virus. Studies on consistency of production would need to take into account the variability inherent in RNA virus replication and assess the presence of minority populations, as revealed for example by the occurrence of mixed base signals in sequencing studies. If minority populations are detected, it will be necessary to assess their biological importance for example by careful comparison in the level of heterogeneity between the master or working seed and higher passage levels e.g. clinical trial material.

The development of any new rotavirus vaccines cannot ignore the events which led to the withdrawal of one vaccine (RotaShield) from the marketplace. RotaShield was introduced in the United States in August 1998 and in less than one year was withdrawn from the marketplace when an epidemiological relationship was established between RotaShield vaccination and intussusception (IS). Early estimates suggested a risk of one case per 2500 children immunized. Re-analysis of the case-control study that examined intussusception and RotaShield revealed that the majority of the cases of IS associated with the first dose occurred in children 4 months of age or older. This did not conform to the manufacturers recommended age at first dose to be given at 2 months of age thus changed the early estimates of attributable risk of IS in the target population (22). The detailed pathogenic mechanisms for IS are not defined but are very likely complex.

GENERAL CONSIDERATIONS

There is considerable understanding on the manufacturing, testing and clinical evaluation of rotavirus vaccines gained from over 20 years of rotavirus vaccine development. Candidate vaccines have been and are currently being studied in a number of countries with diverse economic and geographic boundaries. The regulatory approvals of two rotavirus vaccines and the submissions for approval of one other rotavirus vaccine provide a solid foundation for the preparation of these guidelines and the continued development of new rotavirus vaccines, also enhance the global introduction of rotavirus vaccines. These experiences have set standards for vaccine efficacy, identified safety concerns, highlighted areas of scientific weakness, and introduced new manufacturing technologies and testing strategies. Issues relevant to the development of rotavirus vaccines are highlighted below.

Rotavirus is an acid labile virus and rapidly inactivates at an acid pH with a half-life of less than 12 minutes at pH 2.0. Since rotavirus vaccines are intended to be administered to infants by the oral route, the virus would be inactivated by stomach gastric acid prior to reaching site of infection in the upper gastrointestinal tract. To prevent inactivation of the virus by gastric acid, antacids or buffers are usually administered prior to or in combination with oral rotavirus vaccination. The composition of the antacid and the mode of administration (in combination with vaccine or administered separately) will depend upon the biological characteristics of the vaccine virus.
The processing of live rotavirus vaccines, like many other live viral vaccines, involves cell disruption and, if any, incomplete purification of the virus. In-process adventitious agents inactivation steps are not included for live viral vaccines, since these steps may compromise the live nature of the vaccine itself. As a result, validation of clearance of any adventitious agents may not be possible. For these reasons a comprehensive adventitious agents testing and qualification of the vaccine source materials is essential as part of the vaccine safety control. As with any viral vaccines, production of rotavirus vaccines also involve cells, virus seeds and biological reagents (such as growth supplements, serum, trypsin and any virus stabilizers used in the final product). Hence, each of these vaccine source components must be shown to be free from adventitious agents. The full passage history of the seed materials used for vaccine development needs to identify all substrates through which they have been passed to aid the development of appropriate adventitious agents testing programmes. Viral seed lots should be assessed for absence of adventitious agents from all species that they may have been exposed to from isolation, through passage, and during production, including those that may be present in the raw materials used at each of these stages. Testing will depend on available documentation on cell substrate donor, virus seed passage and derivation history and the seed virus may require purification (molecular cloning, plaque purification etc), if passage and derivation history is uncertain, or contaminated with a known agent.

A TSE risk assessment would need to be included for the seed materials. The revised WHO Guidelines on Transmissible Spongiform Encephalopathies in relation to Biological and Pharmaceutical Products (7) provide guidance on risk assessments for master and working seeds and should be consulted.

Many candidate vaccines are being developed in Vero cells. WHO has set a limit of 10 ng of DNA per human dose for parenterally administered vaccines based upon a WHO risk assessment (4) that established a $2 \times 10^8$ safety factor. For orally delivered vaccines, the acceptable limit of residual cellular DNA has not been previously established, however, recent studies in rats which evaluated the uptake efficiency of Vero cell DNA by the oral and intramuscular route of administration indicated that Vero cell DNA given orally could be found in rat tissues at a concentration of 10,000 fold less than when equivalent amounts of Vero DNA were given parenterally (16), experiments in mice using polyoma DNA also showed a similar uptake difference between the oral and parenteral routes(17). These preliminary data and the lack of evidence that cellular DNA is tumorigenic suggest that a DNA level of 100 µg/dose in an orally administered vaccine is equivalent to that in parenterally administered vaccines. In addition to the quantity of DNA, the size distribution of DNA should be evaluated during manufacturing consistency and process validation. It may be desirable for manufacturers to include steps in the process to reduce the level of high molecular weight cellular DNA. The national regulatory authority may require the further purification of virus harvests derived from continuous cell lines to remove cellular DNA, and/or the use of DNase treatment to reduce the size of DNA fragments. If the virus harvests are derived from diploid cell cultures, further purification is not required.

The concentration of virus can be determined by infectivity titrations, e.g. plaque-forming or focus-forming assays. However, confirming the quantity of each rotavirus serotype in the final mixture of a multivalent as opposed to a single component vaccine is challenging. Conventional infectivity titrations require specific antibody to each of the vaccine components. Molecular methods of measuring virus concentration that do not require the use of specific antibody, such as quantitative real time polymerase chain reaction (PCR), have been developed and are being
evaluated. One method uses Vero cell monolayers seeded in 96-well plates and inoculated with dilutions of a multivalent reference standard and samples. Viral replication is allowed to proceed for 23-24 hours and the cells are subsequently lysed by addition of Triton and one freeze-thaw cycle. Cell lysates are assayed by real time Quantitative Reverse Transcriptase-PCR (QPCR) and rotavirus nucleic acid is quantitated (23). Individual QPCR reactions are performed employing primer/probe sets specific to each of the reassortant strains. Virus concentration is determined by parallel line analysis between the reference standard and each sample. International titration standards do not exist at present and WHO is considering to develop such reagents and their subsequent characterization by international collaborative study. It should be borne in mind however that the differences in the properties of the candidate vaccines in terms of their attenuation may mean that such references will be product specific. Manufacturers should set aside a preparation for use as an in-house standard.

The real time stability of each individual serotype in the final vaccine formulation should be measured to verify that the infectivity titre is at or above that level of virus required for vaccine efficacy at the end of the product shelf-life. The thermal stability of each individual serotype should be determined in an appropriate stability study programme. It is advisable to assign a shelf-life to the intermediates that are intended to be stored on the basis of stability studies. WHO is developing further guidance on this issue. Based on the results of the stability testing programme, an accelerated stability test should be applied to each new batch of vaccine.

If the final product is mixed with vaccine diluent prior to vaccination, the stability of this combination should also be determined.

The consistency of a live virus vaccine manufacturing process can best be determined by monitoring the content and quality of virus produced throughout the process, the level of impurities following processing and stability of the final product. Manufacturers should select relevant parameters based upon the specific production process used and develop corresponding methods to establish such a programme to assure the consistency of production process. For example, the amount of virus produced by a standardized production process and the amount lost during processing should be consistent, the quality of the virus produced can be assessed by its thermal stability profile, the stability of the genomic sequence through multiple cell culture passages may be evaluated, process impurities and residuals such as residual host cell protein, residual cellular DNA, endotoxin, bovine serum, trypsin and antibiotics can be measured and their reduction during processing can be monitored. If the production consistency has been validated, the monitoring programme could be conducted based on a reduced strategy but not on a batch to batch basis with the agreement of the national regulatory authority.

SPECIAL CONSIDERATIONS

Use of primary cells for the production of rotavirus vaccine

Currently the majority of live attenuated rotavirus vaccines that have been developed or are under development are produced in continuous cell lines or diploid cells which are based on the cell bank system, so the main focus of these guidelines involves such situations. But the vaccine production also may occur in primary cells, in such case, the manufacturers should consult additional relevant guidelines or documents to ensure the safety of the final product. However, where suitable alternative cell substrates are available, primary cell cultures are less likely to be used in the future for many reasons (4). The text hereafter provides brief and not full guidance on
issues that need to be considered if primary cells are used for rotavirus vaccine production. In addition, there are some specific issues relating to the production of rotavirus vaccines in primary cell substrates which are not covered in these guidelines.

If vaccine is produced in primary cells obtained directly from trypsinized tissue of normal healthy animals, animals of a species approved by the national regulatory authority and not previously employed for experimental purposes, should be used. However, primary cell cultures prepared from wild animals show a high frequency of viral contamination. The number of isolated viruses and frequency of isolation depend on many factors, including methods of isolation, test cell systems used, number of passages, duration of incubation and co-cultivation, and are directly proportional to the duration of the incubation period of the cultures. The frequency of cell culture contaminations can be reduced by careful screening of the source animals to be used in production for the absence of antibodies to the relevant viruses. The use of animals bred in a carefully controlled colony, especially those which are specific pathogen free, is strongly recommended. In addition, the use of secondary or tertiary cells on which testing for adventitious agents could be performed will reduce the frequency of production cell culture contaminations. Production of uninfected control cultures and the extensive testing required for relevant adventitious agents becomes more challenging when producing live rotavirus vaccines in primary cells.

A live attenuated rotavirus vaccine prepared from primary calf kidney cells has been approved for use in one country. There are no existing WHO guidelines for production of vaccines on primary calf kidney cells. WHO requirements for the use of animal cells as in vitro substrates for the production of biologicals (4) provides general recommendations. WHO recommendations for the production and control of poliomyelitis vaccine (Oral)(7), Guidelines for the production and control of Japanese encephalitis vaccine (live) for human use (13) and Guidelines for the production of candidate live attenuated dengue virus vaccines (14) provide guidance, respectively, on the use of primary cell substrates of monkey, hamster and dog kidney and illustrate the principles that should be followed for vaccines produced in primary cell substrates from other species.

PART A. GUIDELINES ON MANUFACTURING

A.1 Definitions

A.1.1 International name and proper name

The international name should be “Live attenuated rotavirus vaccine (LARV) (oral)” with additions to indicate the virus serotype(s) of the vaccine. The proper name should be equivalent to the international name in the language of the country of origin.

The use of the international name should be limited to vaccines that satisfy the specifications formulated below.
A.1.2 Descriptive definition

Live attenuated rotavirus vaccine (oral) is a sterile, vaccine preparation which contains one or more virus serotypes, which have been grown through a seed lot system, prepared in a suitable approved cell substrate, formulated in a form suitable for oral administration and satisfying all the recommendations formulated in this document.

At least five types of live attenuated rotavirus vaccine have been developed and/or are under development: (i) a candidate rhesus rotavirus strain live attenuated vaccine, (ii) a candidate human-rhesus rotavirus strain live attenuated vaccine, (iii) a human rotavirus strain live attenuated vaccine, (iv) a candidate human-bovine reassortant rotavirus strain live attenuated vaccine, (v) a lamb rotavirus strain live attenuated vaccine. The preparation should satisfy all of the specifications formulated in these guidelines.

Live attenuated rotavirus vaccine with an appropriate stabilizer may be freeze-dried or liquid.

A.1.3 International reference preparations

None are available at present.

A.1.4 Terminology

The definitions given below apply to this document only.

Adventitious agents: Contaminating microorganisms of the virus seed or cell substrate or materials used in its culture, which may include bacteria, fungi, mycoplasmas, and endogenous and exogenous viruses.

Candidate vaccine: A vaccine under development which is used in human clinical trials to assess its safety and efficacy.

Virus master seed lot: A quantity of virus of uniform composition derived from an original isolate, processed at one time and passaged for a documented number of times.

Virus working seed lot: A quantity of virus of uniform composition, derived from the master seed lot by a limited number of passages by a method approved by the national regulatory authority and fully characterized. The virus working seed lot is used for production of vaccine.

Cell seed: A quantity of well-characterized cells, derived from a single tissue or cell of human, animal or other origin, stored frozen in liquid nitrogen in aliquots of uniform composition, one or more of which may be used for the production of a master cell bank.

Cell bank: A cell bank is a collection of ampoules containing material of uniform composition stored under defined conditions, each ampoule containing an aliquot of a single pool of cells.

Master cell bank (MCB): A quantity of fully characterized cells of human, animal or other origin stored frozen in liquid nitrogen in aliquots of uniform composition, derived from the cell seed.
The master cell bank is itself an aliquot of a single pool of cells generally prepared from a selected cell clone under defined conditions, dispensed into multiple containers and stored under defined conditions. The master cell bank is used to derive all working cell banks. The testing performed on a replacement master cell bank (derived from the same cell clone, or from an existing master or working cell bank) is the same as for the initial master cell bank, unless a justified exception is made.

**Working cell bank (WCB):** A quantity of cells of uniform composition derived from one or more ampoules of the master cell bank at a finite passage level, dispensed in aliquots into individual containers appropriately stored, usually stored frozen in liquid nitrogen, one or more of which would be used for production purposes. All containers are treated identically and once removed from storage, are not returned to the stock.

**Production cell culture:** A cell culture derived from one or more ampoules of the WCB or primary tissue used for the production of vaccines.

**Single harvest:** A virus suspension of one virus type harvested from cell cultures prepared from a single production run.

**Monovalent virus pool:** A homogenous pool of multiple single harvests of the same virus serotype, collected into a single vessel before clarification.

**Final bulk:** The finished biological preparation present in the container from which the final containers are filled. The final bulk may be prepared from one or more clarified monovalent virus pools and may contain one or multiple virus serotypes.

**Filling lot (final lot):** A collection of sealed final containers of vaccine that are homogeneous with respect to the risk of contamination during the filling process or freeze-drying. A filling lot must therefore have been filled or prepared in one working session.

**Focus forming unit (FFU):** Viral infectivity identified on cell monolayers using rotavirus-specific antiserum.

**Plaque forming units (PFU):** The smallest quantity of a virus suspension that will produce a plaque in monolayer cell cultures.

**Cell culture infective dose 50% (CCID\textsubscript{50}):** The quantity of a virus suspension that will infect 50% of cell cultures.

**Unit of infectivity (UI):** Relative viral infectivity of a sample inoculated in 96-well Vero cell monolayers measured by Quantitative Reverse Transcriptase-PCR (QPCR) against a defined reference standard preparation.

### A.2. General manufacturing recommendations

The general manufacturing requirements contained in Good Manufacturing Practices for Biological Products (3) should apply to establishments manufacturing oral rotavirus vaccine, with the addition of the following:
Production steps and quality control operations involving manipulations of live rotavirus should be conducted under Biosafety Level 2 (17).

Separate areas or a campaigned programme for the manufacturing of different virus serotypes are required.

In production areas used for bulk formulation and filling, multiple serotypes may be present at the same time and these production areas may be campaigned with other vaccines provided sufficient cleaning validation and product changeover data is provided.

A.3. Control of source materials

A.3.1 Cell cultures for virus production

A.3.1.1 Master cell bank and working cell bank

The use of a continuous cell line such as Vero cells (low passage, non-tumorigenic phenotype) or diploid cells such as fetal rhesus lung cells, FrHL-2 ( well-defined non-tumorigenic phenotype) for the manufacture of rotavirus vaccines should be based on the cell bank system. The cell substrates and cell banks should conform with the WHO requirements for use of animal cells as in vitro substrates for the production of biologicals (4), as appropriate to continuous cells and diploid cells, and should be approved by the national regulatory authority. The maximum number of passages (or population doublings) allowable between the cell seed and the WCB and the production cells should be approved by the national regulatory authority. Additionally, for Vero cells, the MCB or WCB cells should be propagated to or beyond the maximum production level and be examined for the presence of retroviruses and tumorigenicity in an animal test system(4).

WHO has established a cell bank of Vero cells characterized in accordance with the requirements in the report of the WHO Expert Committee on Biological Standardization (4), which is available as a well characterized source material (5) to manufacturers for preparation of their own master and working cell banks on application to the Coordinator, Quality Assurance and Safety of Biologicals, WHO, Geneva, Switzerland.

The Master cell bank is made in sufficient quantities and stored in a secure environment and is used as the source material to make manufacturers working cell banks. In normal practice a master cell bank is expanded by serial subculture up to a passage number (or population doubling, as appropriate) selected by the manufacturer and approved by the national regulatory authority, at which point the cells are combined to give a single pool distributed into ampoules and preserved cryogenically to form the WCB.

The manufacturers working cell bank is used for the preparation of production cell culture, and thus for production of vaccine batches.
A.3.1.1.1 Cell culture medium

Serum used for the propagation of cells should be tested to demonstrate freedom from bacteria, fungi and mycoplasmas, according to the requirements given in Part A, sections 5.2 and 5.3 of the revised Requirements for Biological Substances No. 6 (6), and from infectious viruses. Suitable tests for detecting viruses in bovine serum are given in Appendix 1 of the WHO recommendations for production and control of poliomyelitis vaccine (Oral) (7).

Validated molecular tests for bovine viruses may replace the cell culture tests of bovine sera. As an additional monitor of quality, sera may be examined for freedom from phage and endotoxin. Irradiation may be used to inactivate potential contaminant viruses.

The acceptability of the source(s) of any components of bovine, porcine, sheep or goat origin used should be approved by the national regulatory authority. These components should comply with current WHO guidelines in relation to animal transmissible spongiform encephalopathies (8).

If trypsin is used for preparing cell cultures and aiding in virus infection, it should be tested and found free of cultivable bacteria, fungi, mycoplasmas and infectious viruses, especially bovine or porcine parvoviruses, as appropriate. The methods used to ensure this should be approved by the national regulatory authority. The trypsin should be gamma irradiated if possible.

Human serum should not be used. If human albumin is used, it should meet the revised Requirements for the collection, processing and quality control of blood, blood components and plasma derivatives (Requirements for Biological Substances No.27) (9), as well as current guidelines in relation to human transmissible encephalopathies (8).

Penicillin and other beta-lactams should not be used at any stage of the manufacture. Other antibiotics may be used at any stage in the manufacture provided that the quantity present in the final product is acceptable to the national regulatory authority.

Nontoxic pH indicators may be added, e.g. phenol red in a concentration of 0.002%. Only substances that have been approved by the national regulatory authority may be added.

A.3.1.1.2 Tests on Master and Working Cell Banks

Tests on the master and working cell banks are performed in accordance with WHO requirements for use of animal cells as in vitro substrates for the production of biologicals (4,5). It is important to show that the cell banks are free of adventitious agents relevant to the species used in its derivation. Cell banks should be assessed for absence of adventitious agents that may have been present during production, including those that may be present in the source materials used at each of these stages.

Full characterization may be performed on either the master cell bank or on the working cell bank (4,5).
A.3.2 Virus seeds

A.3.2.1 Virus strains

Virus strains of rotavirus used for master and working seed lots to produce vaccines have in some cases been derived by genetic reassortment of animal rotavirus with human rotavirus with the desired serotypes or in other cases by multiple passages of human rotavirus in cell culture. The seed lot viruses should comply with the specifications of this section. Viruses may be passed in continuous, diploid, and/or primary cell lines. The candidate vaccine strains should be approved by the national regulatory authority.

(1) The strains of rotavirus used in the production of candidate rotavirus vaccines should be identified by historical records, which will include information on the origin of each strain, method of attenuation, whether the strains have been biologically cloned prior to generation of the master seed lots, genetic sequence information, and the passage level at which attenuation for humans was demonstrated by clinical trials.

(2) The vaccine production strain(s) should have been shown by appropriate laboratory tests (see A.3.2.3) and/or clinical studies to yield vaccines that are safe and efficacious in humans Only strains approved by the national regulatory authority should be used.

(3) The immunogenicity of the virus strains, based upon the quantity of infectious virus present of each serotype in the vaccine that induces seroconversion when susceptible individuals are immunized with the vaccine, should be established in a dose-response study. Any potential interference or potentiation between the serotypes in an infectivity assay should be evaluated prior to establishing this value. The immunizing dose established in this way serves as a basis for establishing parameters for potency at the time of release, stability and expiry date.

A.3.2.2 Virus seed lot system

The production of vaccine should be based on the virus master seed lot and virus working seed lot system. Seed lots should be prepared in the same type of cells and by the same production process as those used for production of final vaccine. Virus seed lots should be stored in a dedicated temperature-monitored refrigerator at a temperature that ensures stability and security.

Seed lots of rotavirus used in the production of live attenuated rotavirus vaccine (oral) should be identified by historical records, which should include information on their origin. Only virus seed lots that are approved by the national regulatory authority should be used (see General considerations). The virus master seed lot is generally produced from a biological clone of the attenuated parent virus (animal/human reassortant or cell culture passaged human virus) and is made in sufficient quantities and stored in a secure environment and is used as the source material to make the manufacturers virus working seed lots. Either the virus master seed lots or the virus working seed lots should be fully characterized and be tested extensively for adventitious agents, and approved by the national regulatory authority.

The virus master seed lot also serves as a benchmark from which to compare virus produced by subsequent passage in cell culture or shed virus following vaccination.
The manufacturers virus working seed lot is used for the production of vaccine batches and is prepared from the master virus seed lot. It is recommended that a large lot of virus working seed be set aside as the basic material that the manufacturer should use for the preparation of each batch of vaccine. The virus working seed lot should be prepared by defined number of passage from the virus master seed lot by a method and a passage level from the original virus seed that is established through clinical and vaccine development studies. Once the passage level of the working seed lot is established, it may not be changed without approval from the national regulatory authority.

A.3.2.3 Tests on Virus Master and Working Seed Lots

A.3.2.3.1 Identity

Each seed lot should be identified by virus type by an immunological assay or by sequencing. A molecular identity test, electropherotyping, is one recognized method for identifying rotaviruses. Comparing human and animal rotaviruses and differentiating between subgroups can be achieved through electropherotyping. Electropherotyping can be used as a means by which to identify gross alterations in genomic differences between the parent wild type viruses and/or animal donor virus (if employed) and the vaccine strains. The identity of the vaccine virus is confirmed by comparing the electrophoretic profile of the vaccine virus to the RNA electrophoretic profile of a known human rotavirus serotype. Other molecular identity tests may include RNA/RNA hybridization and enzyme restriction maps or genetic sequences of PCR amplified VP7 gene segments. The tests should be approved by the national regulatory authority.

A.3.2.3.2 Genotype/phenotype characterization

Genotype and phenotype stability of the seed lots upon passage should be measured using relevant assays to ensure uniformity of vaccine lots. Genetic characterization of the viruses has played a major role in the development of the vaccines currently nearing licensure or licensed. It helps to assess the genetic and phenotypic stability of the seed lots on passage, and molecular methods have been used intensively. Other approaches including in vitro phenotypic markers might be considered.

Genetic characterization of the seed lot viruses has included determination of the nucleotide sequence of the complete viral genome, analysis of the molecular basis of the attenuated phenotype and determination of the genetic stability of the virus seed lots by comparison of the nucleotide sequence of the viral genome at different passage levels. It should be noted that full length sequencing may not identify minority populations of variants that may be present in vaccines. In some studies the entire genomic sequence of all 11 gene segments of the virus master seed lot has been sequenced and compared with the sequence of the virus working seed lot, vaccine production lots and vaccine virus shed in stools of vaccinees. If the attenuation loci are known, sequencing around these sites can be performed instead of the entire genome. Given the error frequency of the RNA replicating polymerase, base changes will likely be found. The potential impact of any changes observed (silent or in protein coding regions) should be evaluated.

Specific assays for markers of attenuation are still in development and the manufacturer should make an effort to investigate appropriate assays that are relevant to their vaccine.
A.3.2.3.3 Tests for bacteria, fungi and mycoplasmas

Each virus seed lot should be tested for bacterial, fungal, and mycoplasmal contamination by appropriate tests as specified in Part A, sections 5.2 and 5.3, of the revised Requirements for Biological Substances No. 6 (General Requirements for the Sterility of Biological Substances 1995) (6).

A.3.2.3.4 Tests for adventitious viruses

Each virus seed lot should be tested in cell cultures for adventitious viruses appropriate to the origin and the passage history of the seed virus (12). Neutralization of rotavirus is necessary for many tests because the virus is cytopathogenic. Antisera used for this purpose should be shown to be free from antibodies that may neutralize specific adventitious viruses being tested for. If neutralization of rotavirus is not possible and prior to initiating the assay, the test sample may be passaged in trypsin-free media to reduce the ability of rotavirus to infect the indicator cell substrates. The cells inoculated should be observed microscopically for cytopathic changes. At the end of the observation period, the cells should be tested for haemadsorbing viruses.

Each master or working seed lot should also be tested in animals that may include guinea pigs, mice, and embryonated chicken eggs, as appropriate. For test details refer to the WHO requirements for measles vaccines (Live) (25), and the European Pharmacopoeia, 2002 (12)

Additional testing for specific adventitious viruses may be performed, for example, using polymerase chain reaction (PCR) amplification techniques.

A.3.2.3.5 Virus concentration

Each seed lot will be assayed for infectivity in a sensitive assay in a cell culture system. An immunofocus or plaque forming assay may be used in MA-104, Vero or other sensitive cells to determine virus concentration. The assay is based on the visualization of infected areas (plaques or focus of infection) of a cell monolayer directly or by probing with rotavirus-specific antibodies. Results should be recorded as focus forming units (FFU/ml) or plaque forming units (PFU/ml).

A cell culture infectious dose assay may also be used to determine virus concentration. Results should be recorded as CCID$_{50}$/ml. Alternatively, quantitative PCR detection of virus replication in a cell culture system may be used to provide an appropriate measure of infectivity. Results should be recorded as units of infectivity (UI/ml).

The detailed procedures for carrying out the tests and for interpreting the results should be those approved by the national regulatory authority.

A.4. Control of vaccine production

A.4.1 Control of cell cultures

From the cell suspension used to prepare cell cultures for growing attenuated rotavirus, an amount of processed cell suspension equivalent to at least 5% or 500 ml of cell suspension, whichever is greater, should be used to prepare control cultures of uninfected cells. If fermenter
technology is used, the size and treatment of the cell sample to be examined should be approved by the national regulatory authority.

These control cultures should be observed microscopically for changes attributed to the presence of adventitious agents for at least 14 days after the day of inoculation of the production cultures or at the time of final virus harvest if this is later. The control cultures should be incubated under the essentially similar conditions as the production cultures with agreement of the national regulatory authority. At the end of the observation period, fluids collected from the control culture from each single virus harvest should be tested for the presence of adventitious agents as described below (4.1.2). Samples that are not tested immediately should be stored at -60°C or below.

If any test shows evidence of the presence of adventitious agents in control cultures, the harvest of virus from these cultures should not be used for vaccine production.

For the test to be valid, not more than 20% of the control culture vessels should have been discarded for nonspecific accidental reasons by the end of the test period.

**A.4.1.1 Tests for haemadsorbing viruses**

At the end of the observation period, cells comprising no less than 25% of the control cells should be tested for the presence of haemadsorbing viruses, using guinea-pig red blood cells. If the red blood cells have been stored, the duration of storage should not have exceeded 7 days, and the temperature of storage should have been in the range of 2-8°C.

In some countries, the national regulatory authority requires that additional tests for haemadsorbing viruses will be performed using other species of red blood cells including those from humans (blood group O), monkeys, and chickens (or other avian species). All tests should be read after incubation for 30 minutes at 0-4°C, and again after a further incubation for 30 minutes at 20-25 ºC. The test with monkey red blood cells should be read once more after an additional incubation for 30 minutes at 34-37º C.

For the tests to be valid, not more than 20% of the culture vessels should have been discarded for nonspecific accidental reasons by the end of the test period.

**A.4.1.2 Tests for other adventitious agents**

At the end of the observation period, a sample of the pooled fluid from each group of control cultures should be tested for adventitious agents. For this purpose, 10 ml of each pool should be tested in the same cells, but not the same batch of cells, as those used for the production of virus, and additional 10 ml samples of each pool should be tested in human cells and at least one other sensitive cell system.

Each sample should be inoculated into bottles of these cell cultures in such a way that the dilution of the pooled fluid in the nutrient medium does not exceed 1 in 4. The area of the cells should be at least 3 cm² per ml of pooled fluid. At least one bottle of each kind of the cell cultures should remain uninoculated as a control.
The inoculated cultures should be incubated at a temperature of 35-37°C and should be observed for cytopathic effects for a period of at least 14 days.

For the tests to be valid, not more than 20% of the culture vessels should have been discarded for nonspecific accidental reasons by the end of the test period.

Some national regulatory authorities require that, at the end of this observation period, a subculture by inoculating the fluid onto fresh cells, is made in the same culture system and observed for at least 7 days. Furthermore, some national regulatory authorities require that these cells should be tested for the presence of haemadsorbing viruses.

A.4.1.3 Identity test

At the production level, the cells should be identified by means of tests approved by the national regulatory authority. Suitable methods are, but not limited to, biochemical tests (e.g. isoenzyme analyses), immunological tests (e.g. HLA assays), cytogenetic tests (e.g. for chromosomal markers), and tests for genetic markers (e.g. DNA fingerprinting).

A.4.2. Cell cultures for vaccine production

A.4.2.1 Tests for adventitious agents

On the day of inoculation with the virus working seed lot, each cell culture and/or cell culture control should be examined for degeneration caused by infectious agents. If such examination shows evidence of the presence in a cell culture of any adventitious agents, the culture should not be used for vaccine production. Prior to infection, samples are removed for sterility and mycoplasma testing.

If animal serum is used for cell cultures before the inoculation of virus, it should be removed and replaced with serum-free maintenance medium, after the cells have been washed with serum-free medium, if appropriate.

A.4.2.2 Tests for bacteria, fungi and mycoplasmas

A volume of at least 20 ml of the pooled supernatant fluids from the production cell culture should be tested for bacterial, fungal and mycoplasmal sterility by appropriate tests as specified in Part A, sections 5.2 and 5.3, of the revised Requirements for Biological Substances No. 6 (General Requirements for the Sterility of Biological Substances 1995) (6).

A.4.3 Control of single harvests

A.4.3.1 Virus inoculation

Cell cultures are inoculated with rotavirus working seed at a defined multiplicity of infection. After viral adsorption, cell cultures are fed with maintenance medium and incubated within a defined temperature range and for a defined period of time, usually established based upon the degree of cytopathic effect.
The range of multiplicity of infection (MOI), temperature, pH and time period of incubation will depend on the vaccine strain and production, a defined range should be established by the manufacturer and be approved in the market authorization by the national regulatory authority.

A.4.3.2 Monovalent virus pools

A virus single harvest is harvested within a defined time period post inoculation. A monovalent virus pool may be the result of one or more single harvests (from multiple tissue culture flasks, cell factories or bioreactors) in which all harvests were derived from one or a small number of ampoules of the working cell bank and the same virus working seed lot recovered at the same time. If multiple single harvests are taken, each single harvest should be sampled for testing, stabilized and stored under suitable conditions until pooling. No antibiotics should be added at the time of harvesting or at any later stage of manufacturing. Samples of monovalent virus pools should be taken for testing and stored at a temperature of -60°C or below.

A.4.3.3 Tests on single harvest or monovalent virus pools

Tests may be done on single harvest or on virus pool. If the tests are done on the virus pool, the protocol should be approved by the national regulatory authority.

A.4.3.3.1 Sampling

Samples required for the testing of virus harvests should be taken immediately on harvesting prior to further processing. If the tests for adventitious agents as described in Part A, section A.4.3.3. 4, are not performed immediately, the samples taken for these tests should be kept at a temperature of -60°C or below and subjected to no more than one freeze-thaw cycle.

A.4.3.3.2 Identity

Each single harvest or virus pool should be identified as appropriate rotavirus serotype by immunological assay or by a molecular based assay, e.g. electropherotyping, RNA/RNA hybridization or PCR. The tests should be approved by the national regulatory authority.

A.4.3.3.3 Tests for bacteria, fungi and mycoplasmas

Each single harvest or virus pool should be shown to be free from bacterial, fungal and mycoplasmal contamination by appropriate tests as specified in Part A, sections 5.2 and 5.3, of the revised Requirements for Biological Substances No. 6 (General Requirements for the Sterility of Biological Substances 1995) (6).

A.4.3.3.4 Tests for adventitious agents

For the purposes of the recommendations set out in this section of Part A, the volume of each single harvest or virus pool taken for neutralization and testing should be at least 10 ml and should be such that a total of at least 50 ml or the equivalent of 500 doses of final vaccine, whichever is the greater, has been withheld from the corresponding final bulk.
Each virus pool should be tested in cell cultures for adventitious viruses appropriate to the passage history of the seed virus (12). Neutralization of rotavirus is necessary for many tests because the virus is cytopathogenic. Antisera used for this purpose should be free from antibodies that may neutralize the adventitious viruses being tested for. If neutralization of rotavirus is not possible and prior to initiating the assay, the test sample may be passaged in trypsin-free media to reduce the ability of rotavirus to infect the indicator cell substrates. The cells inoculated should be observed microscopically for cytopathic changes. At the end of the observation period, the cells should be tested for haemadsorbing viruses.

Additional testing for specific adventitious viruses may be performed for example using polymerase chain reaction (PCR) amplification techniques.

A.4.3.3.5 Virus concentration

Each virus pool should be assayed for infectivity in a sensitive assay in cell cultures to monitor the consistency of production.

An immunofocus or plaque assay may be used in MA-104, Vero or other sensitive cells to determine virus concentration. The assay is based on the visualization of infected areas of a cell monolayer directly or by probing with rotavirus serotype-specific monoclonal antibodies. Results will be recorded as focus forming units (FFU/ml) or plaque forming units (PFU/ml).

Alternatively, quantitative PCR detection of virus replication in a cell culture system may be used to provide an appropriate measure of infectivity. Results will be recorded as units of infectivity (UI/ml).

A cell culture infectious dose assay may also be used to determine virus concentration. Results should be recorded as CCID\textsubscript{50}/ml.

The detailed procedures for carrying out the tests and for interpreting the results should be those approved by the national regulatory authority.

A.4.3.3.6 Tests for consistency of virus characteristics

Tests for consistency of virus characteristics are performed during vaccine development, and process validation and not intended for batch release. Examples of studies that might be considered to characterize rotavirus are identified here. Tests should be sought to compare the rotavirus in the harvest pool with the master seed virus, or suitable comparator, to ensure that the vaccine virus has not undergone critical changes during its multiplication in the production culture system. Phenotypic or genotypic characteristics (genomic sequence analysis) may be suitable. Examples to support the consistent quality of the virus produced may include in vitro growth characteristics, thermal stability profile, the amount of infectious (triple shelled) to non-infectious (double shelled) particles produced and the stability of the genomic sequence through multiple cell culture passages.

Other aspects of process consistency may also be monitored and validated, such as process impurities and residuals as residual host cell protein, residual cellular DNA, endotoxin, bovine serum, trypsin, and antibiotics. Their reduction during processing can be monitored to assess
consistency of the manufacturing process. The reduction level should be accepted by the national regulatory authority.

A.4.3.3.7 Storage

Virus pools should be stored at a temperature ensuring stability until formulation.

A.4.3.4 Control of clarified monovalent virus pool (bulk)

The monovalent virus pool may be clarified or filtered to remove cell debris and stored at a temperature that ensures stability before being used to prepare final bulk.

A.4.3.4.1 Sampling

Samples of the clarified virus pool shall be taken immediately after clarification prior to further processing to ensure that no cell or cell debris is left. Samples shall also be tested as described in this section. If not tested immediately, the samples shall be kept at a temperature below -50 °C until testing is done.

A.4.3.4.2 Sterility

The clarified virus pool should be tested for bacterial and fungal sterility according to the requirements in Part A, sections 5.2 of the Requirements for Biological Substances No. 6 (Requirements for the Sterility of Biological Substances)(6), by acceptable methods approved by the national regulatory authority.

A.4.3.4.3 Virus concentration

Each clarified virus pool should be assayed for infectivity in a sensitive assay in cell cultures to monitor the consistency of production.

An immunofocus or plaque assay may be used in MA-104, Vero or other sensitive cells to determine virus concentration. The assay is based on the visualization of infected areas of a cell monolayer directly or by probing with rotavirus serotype-specific monoclonal antibodies. Results will be recorded as focus forming units (FFU/ml) or plaque forming units (PFU/ml).

Alternatively, quantitative PCR detection of virus replication in a cell culture system may be used to provide an appropriate measure of infectivity. Results will be recorded as units of infectivity(UI/ml).

A cell culture infectious dose assay may also be used to determine virus concentration. Results should be recorded as CCID_{50}/ml.

The detailed procedures for carrying out the tests and for interpreting the results should be those approved by the national regulatory authority.
A.4.3.4.4 Tests for residual cellular DNA

For viruses grown in continuous cells, the virus pool should be tested for residual cellular DNA. The removal process, at production scale, should be shown to reduce consistently the level of cellular DNA. The limit should be established and approved by the national regulatory authority. Based on relevant studies in animals, WHO established the acceptable limit of not more than 100µg of cellular DNA per human dose is likely to provide an adequate margin of safety for orally-delivered vaccines. Considerations also should be given to determine the size of residual cellular DNA as part of the validation process.

These tests may be conducted on the final product, in which case, the product should also conform to the specifications described here.

These tests may be omitted as a routine testing, with the agreement of the national regulatory authority, if the manufacturing process is validated to consistently achieve the specification.

A.4.4 Final bulk

The final bulk should be aseptically prepared from one or more serotypes each derived from one or more virus pools obtained from substrates of which control cultures pass the tests specified in Section A.4.1. The virus concentration in the final formulation should be sufficient to ensure the dose which is consistent with that shown to be safe and effective in human clinical trials. The virus pools and final bulk should pass the tests specified in Sections A.4.3.3 and A.4.4.1.

The operations necessary for preparing the final bulk lot should be conducted in such a manner as to avoid contamination of the product.

In preparing the final bulk, any substance such as diluents or stabilizers that is added to the product should have been shown to the satisfaction of the national regulatory authority not to impair the safety and efficacy of the vaccine in the concentration used.

A.4.4.1 Tests on the final bulk

A4.4.1.1 Sterility

Each final bulk suspension should be tested for bacterial and fungal sterility according to Part A, sections 5.2 of the Requirements for Biological Substances 6 (General Requirements for Sterility of Biological Substances) (6), or by a method approved by the national regulatory authority.

A.4.4.2 Storage

Until the bulk is filled into containers, the final bulk suspension should be stored under conditions shown by the manufacturer to retain the desired biological activity.
A.5. **Filling and containers**

The requirements concerning filling and containers given in Good Manufacturing Practices for Biological Products (3) should apply to vaccine filled in the final form.

Care should be taken to ensure that the materials of which the container and, if applicable, transference devices and closure are made do not adversely affect the quality of vaccine and its diluent.

When a freeze-drying process is used for a vaccine production, its validation should be provided to the national regulatory authority for approval.

The manufacturers should provide the national regulatory authority with adequate data to prove the stability of the product under appropriate conditions of storage and shipping.

A.6. **Control tests on final lot**

Samples should be taken from each final lot for the following tests. Both freeze-dried vaccine and its diluent, if applicable, should be tested and fulfil requirements of this section.

A.6.1 **Vaccine**

A.6.1.1 **Inspection of final containers**

Each container in each final lot should be inspected visually and those showing abnormalities should be discarded.

A.6.1.1.1 **Appearance**

Visual inspection of the appearance of the freeze-dried or liquid vaccine should be described with respect to the form and colour. In case of freeze-dried vaccines, visual inspection should be performed on the freeze-dried vaccine, on its diluent and on the reconstituted vaccine. If reconstitution with the product diluent does not allow for the detection of particulates, an alternative diluent may be used.

A.6.1.2 **Identity**

The virus in one or more individually labelled final containers should be identified as rotavirus and, for multivalent vaccine formulations each serotype should be identified, by appropriate methods approved by the national regulatory authority. Methods such as plaque neutralization, immunofocus assays in cell culture are suitable to identify the presence of rotavirus using rotavirus-specific polyclonal antiserum. PCR may also be appropriate, in this case the virus titration by quantitative PCR may serve as the identity test.

A.6.1.3 **Sterility**

Liquid or reconstituted vaccine should be tested for bacterial and fungal sterility according to the requirements in Part A, sections 5.2 of the Requirements for Biological Substances No. 6
(Requirements for the Sterility of Biological Substances)(6), by acceptable methods approved by the national regulatory authority.

A.6.1.4 pH

The pH value of the final lot should be tested in a pool of final containers and an appropriate limit set to guarantee virus stability. In case of freeze-dried vaccines, it should be done after reconstitution of the vaccine with the diluent.

A.6.1.5 Residual Moisture

The residual moisture in a representative sample of each freeze-dried lot should be determined by a method approved by the national regulatory authority and an appropriate limit set to ensure the vaccine stability.

A.6.1.6 Virus concentration

The virus concentration in each of at least three final containers of the rotavirus vaccine final lot will be assayed for infectivity individually in a sensitive assay system in which interference or potentiation between the serotypes present in the vaccine does not occur.

An immunofocus or plaque assay may be used in MA-104, Vero or other sensitive cells to determine virus concentration. The assay is based on the visualization of infected areas of a cell monolayer directly or by probing with rotavirus serotype-specific monoclonal antibodies. Results will be recorded as focus-forming units (FFU/ml) or plaque forming units (PFU/ml).

If immunological based assays are used, the specificity and lack of cross reactivity of the antiserum must be verified.

Alternatively, quantitative PCR detection of virus replication in a cell culture system may be used to provide an appropriate measure of infectivity. Results will be recorded as units of infectivity (UI/ml).

A cell culture infectious dose assay may also be used to determine virus concentration. Results should be recorded as CCID$_{50}$/ml.

The titre of each individual serotype will be determined and should fall within specifications for potency. The assay method should include suitable qualified reference reagents for each serotype in the vaccine.

The detailed procedures for carrying out the tests and for interpreting the results should be those approved by the national regulatory authority.

The national regulatory authority should approve a reference preparation of live attenuated rotavirus vaccine for use in tests to determine virus concentration.

Freeze-dried vaccines should be reconstituted with its diluent to determine virus concentration. A validated alternative diluent may be needed since the approved diluent may be toxic to the cell cultures used in the assay. If a different diluent is used for this test, data of
comparison between results with both diluents should be submitted for the approval of the national regulatory authority.

Internal consistency limits should be established by the manufacturer taking into account the vaccine dose shown to be safe and effective in human clinical trials. Specifications for virus concentration should essentially specify the minimum titre guaranteed to be contained in one human dose and agreed with the national regulatory authority.

A.6.1.7 Accelerated stability tests

A representative number of the final containers should be exposed to an elevated temperature for a defined time period, using conditions based on the manufacturer's experience. The geometric mean of infectious virus titre of the containers that have been exposed should not have been decreased by more than a specific amount during the period of exposure. Virus titre estimation of non-exposed and exposed vials should be made in parallel and results expressed in terms of PFU, FFU, CCID₅₀ or UI (unit of infectivity) per human dose. The maximum allowable loss of titre during the accelerated stability test should be confirmed on the basis of the manufacturer’s experience and approved by the national regulatory authority. For a multivalent vaccine, if there is no significant difference in the virus loss between serotypes, the loss may be based upon total virus concentration.

A.6.2 Diluents

The requirements given in Good Manufacturing Practices for Pharmaceutical Products (10) should apply for the manufacturing and control of diluents used to reconstitute live attenuated rotavirus vaccines and, if required, the antacid buffer used. An expiry date should be established for the diluent based upon stability data. If an antacid is to be used, the stability of the rotavirus in the presence of the antacid should be confirmed. For lot release of the diluent, tests for identity, description, pH, volume, sterility, and the content of key components should be done.

A.7 Records

The requirements given in Good Manufacturing Practices for Biological Products (3) should apply.

A.8 Samples

The requirements given in Good Manufacturing Practices for Biological Products (3) should apply.

A.9 Labelling

The requirements given in Good Manufacturing Practices for Biological Products (3) should apply, with the addition of the following.

The label on the carton enclosing one or more final containers, or the leaflet accompanying the container, should include the following information:
A statement that the candidate vaccine fulfils Part A of these Guidelines;

- A statement of the nature of the preparation, specifying the designation of the strain(s) of rotavirus contained in the vaccine, the minimum amount of virus contained per human dose, the origin of the substrates used in the preparation of the vaccine and whether the vaccine strains were derived by molecular methods;
- The fact that the vaccine is not to be injected;
- A statement of the nature and quantity, or upper limit, of any antibiotic present in the vaccine;
- An indication that contact with disinfectants is to be avoided;
- A statement regarding the concomitant administration of rotavirus vaccine with other oral vaccines such as oral poliovirus vaccine and with other non-orally administered vaccines;
- A statement concerning administration to HIV positive or other immunocompromised individuals;
- A statement indicating the volume and nature of the diluent to be added in order to reconstitute the vaccine, and specifying that the diluent to be used is that supplied by the manufacturer;
- A statement that after the vaccine is reconstituted, it should be used without delay, or if not used immediately, stored under defined conditions and in the dark for a maximum period defined by stability studies;
- A statement concerning storage conditions (temperature), expiry date, volume and instructions of reconstitution. Only one storage temperature and expiry date should be stated on the label and leaflet;
- A statement indicating if an antacid is to be given prior to or in combination with the vaccine at the time of vaccination.

It is desirable for the label or the leaflet to carry the names both of the producer and of the source of the bulk material if the producer of the final vaccine did not prepare it, and also the final conditioning.

A.10. Distribution and shipping

The requirements given in Good Manufacturing Practices for Biological Products (3) should apply.

Shipments should be at the approved temperatures and parcels should contain cold-chain monitors. For some products, freezing of the diluent should be avoided.

A.11. Storage and expiry date

The statements concerning storage temperature and expiry date of the vaccine and its diluent, if applicable, appearing on the label and in the leaflet, as recommended in Good Manufacturing Practices for Biological Products (3), should be based on experimental evidence and should be submitted for approval to the national regulatory authority.
A.11.1 Storage conditions

Before being distributed by manufacturing establishment or before being issued from a storage site, the vaccine should be stored at a temperature shown by the manufacturer to be compatible with a minimal titre loss. The maximum duration of storage should be fixed with the approval of the national regulatory authority and should be such as to ensure that all quality specifications for final product including the minimum titre specified on the label of the container (or package) will still be maintained until the end of the shelf-life.

A.11.2 Expiry date

The expiry date should be defined on the basis of shelf-life supported by the stability studies with the approval of the national regulatory authority and should relate to the date of the last satisfactory determination, performed in accordance with Part A, section A.4.3.3.5, of virus concentration, i.e. the date on which the test system was inoculated. The expiry date for the vaccine and the diluent may be different.

PART B. NONCLINICAL EVALUATION OF LIVE ATTENUATED ROTAVIRUS VACCINES

Non-clinical evaluation of rotavirus vaccines should be based on existing WHO guidelines (1); however, the following rotavirus specific issues should be considered.

For animal studies, there is a need to use oral dosing with antacid which corresponds to that intended for use in clinical trials; for example, in mice or in rats (using a strain of rat susceptible to human rotavirus infection) with the full human dose of vaccine. As rotavirus is not neurotropic, and neural tissue passage has not been used in the derivation of any of the vaccine strains, the neurovirulence test for each batch is not justified, nor is there a need to test the master or working seed lots. As with all live attenuated vaccines, special attention should be given to evaluate the stability of attenuation phenotype by appropriate \textit{in vitro} and \textit{in vivo} assays. Non-clinical experimental studies to predict risks from excreted vaccine virus are not expected to be informative.

Manufacturers should evaluate, based on a review of the literature, any risks to humans or animals if the vaccine virus is subsequently shown to be shed from vaccinees, taking into account the likelihood of excreted vaccine virus reassorting with wildtype viruses. Finally, the pathogenic mechanisms of intussusception associated with oral rotavirus vaccination are currently unknown and no animal model readily exists to evaluate the risk of intussusception. Nevertheless, manufacturers should keep abreast of the evolving scientific knowledge and plan their pre-clinical vaccine evaluation strategy accordingly.
PART C. CLINICAL EVALUATION OF LIVE ATTENUATED ROTAVIRUS VACCINES

The WHO guidelines on regulatory expectations for clinical evaluation are appropriate for development of rotavirus vaccines (2) with considerations given to the following rotavirus specific issues.

C.1 Immune Responses to Rotavirus

Live attenuated rotavirus vaccines have been developed based on evidence that natural rotavirus infections elicit protective immune responses, particularly against future severe rotavirus disease. For a period after rotavirus vaccination, much of the serum IgA is rotavirus-specific, so that rotavirus serum IgA levels act as a measure of seroconversion. Also, rotavirus serum IgA antibody responses have been used as measures of vaccine immunogenicity of all candidate live attenuated rotavirus vaccines evaluated so far. Thus rotavirus serum IgA antibody responses should be recorded for other vaccine candidates.

Nevertheless it should be noted that rotavirus serum IgA is not an immune correlate of protection for rotavirus vaccines. A role for neutralizing antibody in protective efficacy has been suggested, but the correlation between neutralizing antibody titres and clinical efficacy has not been demonstrated. These data have been recently reviewed for the different live attenuated rotavirus vaccine candidates (20).

C.2 There are additional specific issues that may affect the safety and efficacy of oral rotavirus vaccines. Criteria which are considered important for evaluation pre-licensure include the following:

C.2.1 Vaccine Virus Shedding and Transmission

Manufacturers should undertake studies to determine the amounts of the vaccine virus (if applicable by serotype) shed from vaccinees, the duration of shedding and should assess the transmissibility of vaccine strains to the unvaccinated during clinical studies of safety and efficacy. If vaccine virus is shed in sufficient quantities that transmission is feasible and/or if transmission from vaccines is demonstrated then studies of the likelihood of reversion to wild type and the likelihood of the vaccine virus reassorting with wild-type rotaviruses are indicated.

C. 2.2 Dose Regimen

Clinical trials should be designed to determine the number of doses to be administered to elicit a measurable immune response and clinical efficacy. Based on experience to date, at least two or three doses of live attenuated oral rotavirus vaccines are necessary to overcome interfering factors which may include maternal antibodies or concomitant administration of OPV.

C. 2.3 Concomitant Administration with Routine Childhood Vaccines

As it is intended that live attenuated rotavirus vaccines would be incorporated within routine childhood immunization programmes, it is important to generate information on immune responses on co-administration with the routine childhood vaccines at the target ages of
administration. In particular, co-administration should be studied with OPV, as both are live attenuated oral vaccines.

C.2.4 Vaccine Safety

After licensure of a rhesus reassortant rotavirus vaccine, post-marketing surveillance in one country revealed an association with intussusception, a rare serious adverse event, in infants administered the vaccine. This occurred in infants given the vaccine at an older age than that recommended by the manufacturer. Due to this experience, rotavirus vaccines must be assessed for any vaccine-attributable intussusception within 30 days after each dose of vaccine. However, even very large pre-licensure studies (for example in 70,000 infants) cannot rule out an association between vaccine and intussusception. They can only estimate the relative and absolute risk compared to placebo with generation of 95% confidence intervals that give an idea of the degree of risk that cannot be excluded. Such data are generated in clinical trials in selected populations and in which the doses of the regimen under study are controlled, so that the data may not predict risk in the post-licensure period. If post-licensure studies, currently ongoing, reveal an age-related risk of vaccine-attributable intussusception,, specifications may need to be considered for the age of first dose of vaccine (21).

In planning the size of future clinical safety trials for a new rotavirus vaccine, assumptions need to be made about the likely background incidence of intussusception. However, it may not be feasible to obtain accurate data on naturally occurring intussusception in all countries in which a study is to be performed. The calculation should state the degree of risk of vaccine-associated intussusception that the study should be able to assess. With appropriate justifications, sample sizes of <70,000 for future pre-licensure clinical trials of new rotavirus vaccines may be acceptable.

C.2.5 Definition of Clinical Endpoint in Trials of Protective Efficacy

Results from clinical trials to date, show that rotavirus vaccines are more efficacious against severe illness than mild or moderate disease. Standard definitions of (a) a diarrhea episode and (b) the severity of illness (recommended as the primary endpoint of efficacy studies) are critical. Several methods for assessing the "severity" of rotavirus infection are available, for example, based on the scale described by Ruuska et al (22) and Clark et al (24). Hospitalization may not be appropriate as the only endpoint because this is a context-sensitive situation which may not reflect, in all cases, the severity of illness. However, hospitalization combined with grading of severity on an appropriate scale should give comparable results between study sites.

Usually the primary analysis is focused on prevention of acute rotavirus gastroenteritis due to the serotype(s) in the vaccine. It is acceptable that such primary analysis be based on those cases of acute rotavirus gastroenteritis that occur from 14 days onwards after administration of the last dose of the tested regimen. Considerations should also be given to sensitivity analysis to investigate efficacy against all acute rotavirus gastroenteritis that occurs from the time of the first dose onwards.
C.2.6 Other Factors

Several other factors need to be considered when assessing new rotavirus vaccines, although some of these data may be generated post-licensure. For example, data on use in special populations, and in diverse geographical regions (developed/developing country settings), and interference of other health factors.

C.2.6.1 Vaccine Safety in Immunocompromised Infants

Data on immunocompromised children are currently not available. As with other live vaccines, live attenuated rotavirus vaccines should be shown to be safe in HIV-infected infants prior to general implementation in countries with high HIV prevalence. Natural rotavirus infection has not been shown to be more serious or associated with increased safety risks in HIV-infected infants than in non-HIV-infected infants, although slightly longer shedding of rotavirus was observed in one study.

C.2.6.2 Seasonality of Rotavirus Infection

Depending on where pre-licensure efficacy data were generated (ie in areas with seasonal or year round rotavirus infection), it may be appropriate to generate further data in alternative geographical areas. For example, in those settings with a marked seasonal pattern, rotavirus vaccine efficacy may be higher when it is administrated shortly before the peak period for rotavirus circulation, possibly due to a booster effect of natural infection during the season. For this reason, analysis to assess efficacy in sequential seasons may yield useful information.

C.2.6.3 Diverse Geographical and Population Settings

Rotavirus vaccine efficacy and/or effectiveness needs to be studied in diverse geographical regions with different populations and different socio-economic conditions. Generally, data from clinical trials conducted in one part of the world would not necessarily be predictive of vaccine efficacy in other parts of the world(15). For example, clinical trials have shown variable levels of rotavirus-specific serum IgA with the same vaccine in developed and less developed or developing country populations. Furthermore, the assessment of protection provided by each serotype in the vaccine and/or against serotypes not in the vaccine (i.e cross-protection) is inherently limited by the serotypes circulating in the countries where the study/studies was/were done during the observation period. Studies may not be powered to demonstrate efficacy by specific serotype in which circumstance data must be assessed on a case by case basis when considering any claims for vaccine serotype specific and heterotypic protection.

There are likely to be many factors which are responsible for differences in observed immunogenicity and protective efficacy of the rotavirus vaccines in diverse geographical settings. In designing rotavirus vaccine trials (pre- or post-licensure), consideration should be given to control for possible effects of factors such as the predominant circulating rotavirus serotypes, other vaccinations, malnutrition, vitamin and mineral deficiencies, multiple enteric infections, malaria, parasitic infections, HIV, hepatitis, immunodeficiencies, maternal vertically-passed antibodies and breast feeding.
C.2.6.4 Interchangeability

At present there are no data on safety, immunogenicity or efficacy when more than one vaccine type is used in one infant in the priming series. Although there may be difficulties of interpreting immunogenicity data in terms of predicting efficacy and of complexities that would arise in studies of safety and efficacy when more than one vaccine type is given (e.g. a monovalent human rotavirus strain live attenuated vaccine followed by a multivalent human-bovine reassortant rotavirus strain live attenuated vaccine), such data would be welcome.

C.3 Post-marketing Studies and Surveillance

Large scale post marketing surveillance studies of safety and effectiveness are indicated once vaccines are approved. In the case of rotavirus, knowledge of strain distribution, establishment of country-specific laboratory expertise and education of physicians and policymakers will be required to effectively execute these studies. The aims of post marketing surveillance of rotavirus vaccines may include evaluation of vaccine effectiveness in different populations and in settings with more varied rotavirus serotypes predominating, the impact of emerging strains of rotavirus, monitoring the risk of vaccine-associated intussusception and of other potential adverse events, and evaluation of compliance with the recommended vaccination schedule. A standardized protocol for post-marketing surveillance is under development.

PART D. GUIDELINES FOR NATIONAL REGULATORY AUTHORITIES

D.1. General

The general recommendations for control laboratories given in the Guidelines for National Authorities on Quality Assurance for Biological Products (11), which specify that no new biological substance should be released until consistency of manufacturing and quality as demonstrated by a consistent release of batches has been established, should apply.

The detailed production and control procedures and any significant changes in them should be discussed with and approved by the national regulatory authority. The national regulatory authority should obtain the working reference from manufacturers to establish a national working reference preparation until an international reference reagent is available.

D.2 Release and certification

A vaccine lot should be released only if it fulfils the national requirements and/or Part A of the present Guidelines. A protocol based on the model given in Appendix 1, signed by the responsible official of the manufacturing establishment, should be prepared and submitted to the national regulatory authority in support of a request for release of vaccine for use.

A statement signed by the appropriate official of the national control laboratory should be provided if requested by a manufacturing establishment and should certify whether or not the lot of vaccine in question meets all national requirements, as well as Part A of these guidelines. The certificate should also state the lot number, the number under which the lot was released, and the number appearing on the labels of the containers. In addition, the date of the last satisfactory determination of virus concentration as well as assigned expiry date on the basis of shelf life
should be stated. A copy of the official national release document should be attached. The certificate should be based on the model given in Appendix 2.

The purpose of the certificate is to facilitate the exchange of live attenuated rotavirus vaccines between the countries.
AUTHORS

The first draft of these guidelines (WHO/BS/05.2014) was prepared by Drs PD Minor, National Institute for Biological Standards and Control, Potters Bar, UK; ML Pombo, Instituto Nacional de Higiene Rafael Rangel, Control of Vaccines and Recombinant Department, Caracas, Venezuela; W Wainwright, Rotavirus Vaccine Program, PATH, Seattle, USA; with support from the WHO Secretariat (Drs DJ Wood and TQ Zhou, QSB/IVB/FCH).

A revised draft was prepared by Drs R Dobbelaer, Biological Standardization, Scientific Institute of Public Health – Louis Pasteur, Belgium; PD Minor, National Institute for Biological Standards and Control, Potters Bar, UK; ML Pombo, Instituto Nacional de Higiene Rafael Rangel, Control of Vaccines and Recombinant Department, Caracas, Venezuela; W Wainwright, Rotavirus Vaccine Program, PATH, Seattle, USA; with support from the WHO Secretariat (Drs DJ Wood and TQ Zhou, QSB/IVB/FCH; Drs M.P Kieny and D Steele, IVR/IVB/FCH; Dr A Bentsi-Enchill, VAM/IVB/FCH and Dr L Chocarro, ATT/IVB/FCH).
ACKNOWLEDGEMENTS

For the first draft of these guidelines, acknowledgements are due to the following participants at a WHO informal consultation on quality, safety and efficacy specifications for live attenuated rotavirus vaccines held in México, D.F., México in February 2005 (14):

Dr Chintimani D. Atreya, Center for Biologics Evaluation and Research, Food and Drug Administration, Rockville Pike, Bethesda, USA
Dr Liliana Chocarro, Access to Technologies, World Health Organization, Geneva, Switzerland
Dr Ma. de los Angeles Cortes, Regional Office for the Americas, Washington, USA
Dr Roland Dobberlaer, Head, Biological Standardization, Scientific Institute of Public Health Louis Pasteur, Brussels, Belgium
Dr Manuel Franco, Instituto de Genetica Humana, Pontificia Universidad Javeriana, Bogota, Colombia
Dr Roger Glass, Chief, Viral Gastroenteritis Section, Centers for Disease Control and Prevention Atlanta, USA
Dr Harry Greenberg, Senior Associate Dean for Research, Stanford University School of Medicine and the VAPAHCS, Stanford, USA
Dr C. Lecomte, Glaxo SmithKline Biologicals, Rixensart, Belgium
Dr A. MacLean, Director, Q Gen, Cooperative Res. Centre for Vaccine Technology, Queensland Institute of Medical Research, Brisbane, Queensland, Australia
Dr Philip Minor, Head, Division of Virology, National Institute for Biological Standards and Control, Blanche Lane, Potters Bar, United Kingdom
Dr Isabel Perez-Schael, Chief of Section, Institute of Bio-medicine, Caracas, Venezuela
Dr Maria Luz Pombo, Instituto Nacional de Higiene Rafael Rangel, Control of Vaccines and Recombinant Department, Caracas, Venezuela
Mr S. Prasad, Bharat Biotech International Ltd., Hyderabad, India
Dr L.P. Ruiz Jr., BIOVIRx Inc, Shoreview, USA

APPENDIX 1

Summary protocol of manufacturing and control of live attenuated rotavirus vaccine (oral)

The following protocol is intended for guidance, and indicates the information that should be provided as a minimum by the manufacturer to the national regulatory authority. The protocol must be accompanied by a lot release certificate from the licensing authority which may or may not be the country of manufacturing origin. Information and tests may be added or deleted as required by the national regulatory authority of the importing country, if applicable.

It is thus possible that a protocol for a specific product may differ in detail from the model provided. The essential point is that all relevant details demonstrating compliance with the license and with the relevant WHO guidelines of a particular product should be given in the protocol submitted.

The section concerning the final product must be accompanied by a sample of the label and a copy of the leaflet that accompanies the vaccine container. If the protocol is being submitted in support of a request to permit importation, it must also be accompanied by a lot release certificate from the national regulatory authority of the country in which the vaccine was produced stating that the product meets national requirements as well as Part A guidelines of this document published by WHO.

Summary information on the finished product (final lot)

International Non-Proprietary name  Live attenuated rotavirus vaccine (oral)

Commercial name
Product license (Marketing Authorization) number
Country:
Name and address of manufacturer
Name and address of license holder if different
Final packing lot number
Type of containers
Number of containers in this packing lot
Final container lot number
Number of filled containers in this final lot
Date of filled containers in this final lot
Date of manufacture (Filling or lyophilizing, if applicable)

Date on which last determination of virus concentration was started

Shelf-life approved (months)
Expiry date
Storage conditions
Volume of single dose

Volume of vaccine per container

Number of doses per container

Virus concentration per human dose:
  Serotype ________  ____________
  Serotype ________  ____________
  Serotype ________  ____________
  Serotype ________  ____________

Nature of any antibiotics present in vaccine and amount per human dose __________

Production cell substrate __________

Bulk No. of monovalent virus pools blended in multivalent vaccine (if applicable)

Diluent or Antacid (if applicable)
  Lot number __________
  Date of manufacture __________
  Expiry date __________

Attach a genealogy of the lot numbers of all vaccine components used in the formulation of the final product, diluent and antacid will be informative. An example of a genealogy can be found in Appendix 2.

The following sections are intended for the reporting of the results of the tests performed during the production of the vaccine, so that the complete document will provide evidence of consistency of production; thus if any test has to be repeated, this must be indicated. Any abnormal results should be recorded on a separate sheet. If any cell lot, virus harvest or other intermediates intended for production of the current lot was rejected, this should also be recorded either in the following sections or on a separate sheet.
A.3 CONTROL OF SOURCE MATERIALS

Results of tests on the same master or manufacturing working cell bank and the same virus master and manufacturing working seed lots are submitted to and approved by the national regulatory authority during the procedure for granting the licensing or its variations and need not be resubmitted at the time of lot release.

A.3.1 Cell cultures for virus production

| Name and identification of cell substrate | ________________________________ |

Certification by the manufacturer

Name of head of production (typed) _______________________________________________

Certification by the person from the control laboratory of the manufacturing company taking over responsibility for the production and control of the vaccine:

I certify that lot No: ______________ of live attenuated rotavirus vaccine (oral), whose number appears on the label of the final container, meets all national requirements and satisfies Part A of the Requirements for Biological Substances No. _____ of live attenuated rotavirus vaccines (oral).

Signature ______________________________

APPENDIX 3

Model certificate for the release of live attenuated rotavirus vaccines

This certificate is to be provided by the national regulatory authority of the country where the vaccines have been manufactured, upon request by the manufacturer

Certificate Nº ________________

LOT RELEASE CERTIFICATE

The following lot(s) of live attenuated rotavirus vaccine (oral) produced by ________________________ in ______________, whose numbers appear on the labels of the final containers, meet all national requirements and Part A of Requirements for Biological Substances No. ___ (Requirements for Live Attenuated Rotavirus Vaccine (oral)), revised ______, and comply with Good Manufacturing Practices for Pharmaceutical Products and Good Manufacturing Practices for Biological Products.

As a minimum, this certificate is based on examination of the summary protocol of manufacturing and control.

The Director of the National Regulatory Authority (or Authority as appropriate):

Name (Typed)          ------------------------
Signature             ------------------------
Date                  ------------------------

_____________________________________________________________________________

1 Name of manufacturer
2 Country of origin
3 If any national requirements are not met, specify which one(s) and indicate why release of the lot(s) has nevertheless been authorized by the national regulatory authority
4 With the exception of provisions on distribution and shipping, which the national regulatory authority may not be in a position to assess.
5 WHO Technical Report Series, No. ____, YYYYY, Annex __.
