Rotavirus disease and vaccines in Burundi

In Burundi, diarrhea causes approximately 15 percent of deaths in children less than five years of age.\(^1\) Rotavirus, the most common cause of severe and fatal diarrhea in young children worldwide, takes the lives of more than 3500 Burundian children less than five each year.\(^2,3\) It is estimated that one third of all under-five diarrheal disease hospitalizations in Burundi are caused by rotavirus.\(^2\) Studies in Africa show that rotavirus vaccines are safe and effective against severe rotavirus disease and are cost-effective.\(^4-6\)

On December 16, 2013, Burundi will become the 19\(^{th}\) GAVI-eligible country to introduce rotavirus vaccines in its national immunization program. The burden of rotavirus disease in Burundian children, coupled with the power of rotavirus vaccines to prevent childhood deaths and hospitalizations, underscores the potential for Burundi’s introduction of rotavirus vaccines to save children’s lives.

**ROTAVIRUS TREATMENT AND PREVENTION STRATEGIES**

Rotavirus is highly contagious and spreads easily from person-to-person through contaminated hands and objects. It cannot be treated with antibiotics or other drugs. Mild rotavirus infections can be treated effectively in the same manner as other forms of diarrhea, by providing fluids and salts (oral rehydration therapy). However, children with severe rotavirus diarrhea can become dehydrated and often need intravenous fluids or they risk dying. In developing countries, this type of urgent health care is often inaccessible or unavailable, making rotavirus prevention through vaccination critical to saving lives.

Vaccination is the best way to prevent severe rotavirus disease and the deadly, dehydrating diarrhea that it causes. Improvements in water quality, hygiene, and sanitation stop bacteria and parasites that cause other forms of diarrhea but do not prevent the spread of rotavirus. Lifesaving rotavirus vaccines should be introduced as part of a comprehensive approach to control diarrhea, along with other interventions including oral rehydration therapy, breastfeeding, zinc treatment, and improvements in water and sanitation.

**TWO SAFE AND EFFECTIVE ROTAVIRUS VACCINES ARE SAVING LIVES TODAY**

There are currently two orally administered rotavirus vaccines available: Rotarix\(^8\), manufactured by GlaxoSmithKline, and RotaTeq\(^8\), manufactured by Merck & Co., Inc. Both vaccines have been shown to be safe and effective in large-scale clinical trials in Africa, Asia, Europe, Latin America, and the US. Clinical trials in Africa (South Africa, Ghana, Kenya, Malawi, and Mali) found that rotavirus vaccines reduced severe rotavirus disease by more than 60 percent during the first year of life, when children are at greatest risk of severe rotavirus disease.\(^4,5\)
In June 2009, based in part on results from clinical trials in Africa demonstrating that rotavirus vaccines significantly reduced rotavirus disease in impoverished, high-mortality settings, the WHO Strategic Advisory Group of Experts recommended that rotavirus vaccines be included in all countries’ national immunization programs. As of December 16, 2013, 51 countries have introduced rotavirus vaccines in their national immunization programs, including 13 in Africa. Fourteen additional countries in Africa have been approved by GAVI for rotavirus vaccine support: Angola, Cameroon, Central African Republic, Republic of the Congo, Djibouti, Eritrea, Guinea-Bissau, Kenya, Madagascar, Mali, Niger, Sierra Leone, Togo, and Zimbabwe.

Rotavirus vaccines are saving lives and improving health in countries where children have access to them. Swift and significant declines in hospitalizations and deaths due to rotavirus and all-cause diarrhea have been observed in many countries with rotavirus vaccines in their national immunization programs. Rotavirus vaccines may protect unvaccinated children and adults by reducing spread of rotavirus (an effect called herd immunity).

INTEGRATED TOOLS TO FIGHT DIARRHEA IN BURUNDI

Rotavirus vaccines represent the latest step in Burundi’s implementation of comprehensive diarrhea control strategies. Between 2004-2010, Population Services International distributed and marketed oral rehydration solution (ORS) in Burundi under the brand Orasel® as part of a USAID-funded project. This project significantly increased knowledge of danger signs of dehydration from diarrhea and methods of treatment including use of ORS.

The Integrated Global Action Plan for the Prevention and Control of Pneumonia and Diarrhea (GAPPD) is a plan to combat diarrhea and pneumonia together through protection, prevention, and treatment strategies. These strategies are reflected in Burundi’s ORS marketing, as well as in its introduction of pneumococcal vaccines in 2011 with GAVI support. With the addition of rotavirus vaccines, Burundi is taking another step toward operationalizing the GAPPD approach, and will be equipped with the tools to prevent deadly rotavirus diarrhea in young children.

ROTAVIRUS VACCINES ARE COST-EFFECTIVE AND A WISE INVESTMENT

Rotavirus vaccines are cost-effective, and in GAVI-eligible countries, where 95 percent of deaths due to rotavirus occur, more than 2.4 million child deaths can be prevented by 2030 by accelerating access to lifesaving rotavirus vaccines. If used in all GAVI-eligible countries, rotavirus vaccines could prevent an estimated 180,000 deaths and avert 6 million clinic and hospital visits each year, thereby saving US $68 million annually in treatment costs.

Rotavirus vaccines are an essential, lifesaving intervention in comprehensive diarrhea control. Accelerating access to rotavirus vaccines will not only save the lives of Burundian children but also lessen the heavy economic and health burden of rotavirus disease, contributing to poverty reduction and economic growth. GAVI and its partners plan to support the introduction of lifesaving rotavirus vaccines in more than 30 of the world’s poorest countries by 2015.
